Blockchain-based Data Access Environment for Disaster Risk Reduction

Jon Berkeley

24 October 2022

Neil H. Wasserman

Adjunct Faculty, Computer Science Dept.

Blockchain-based data access for DRR - Agenda

- Why blockchain?
- The goal: better models for DRR – What if we could prepare better, respond better, build resilience communities in the face of growing threats?
- The urgency
- Blockchain connection to DRR
- What the future environment could look like – the data-sharing ecosystem
- Experimental first steps

Growing need for better models and techniques for DRR

Floods in Pakistan

15 inches rain now versus normal 5 inches;
1/3 of Pakistan is underwater

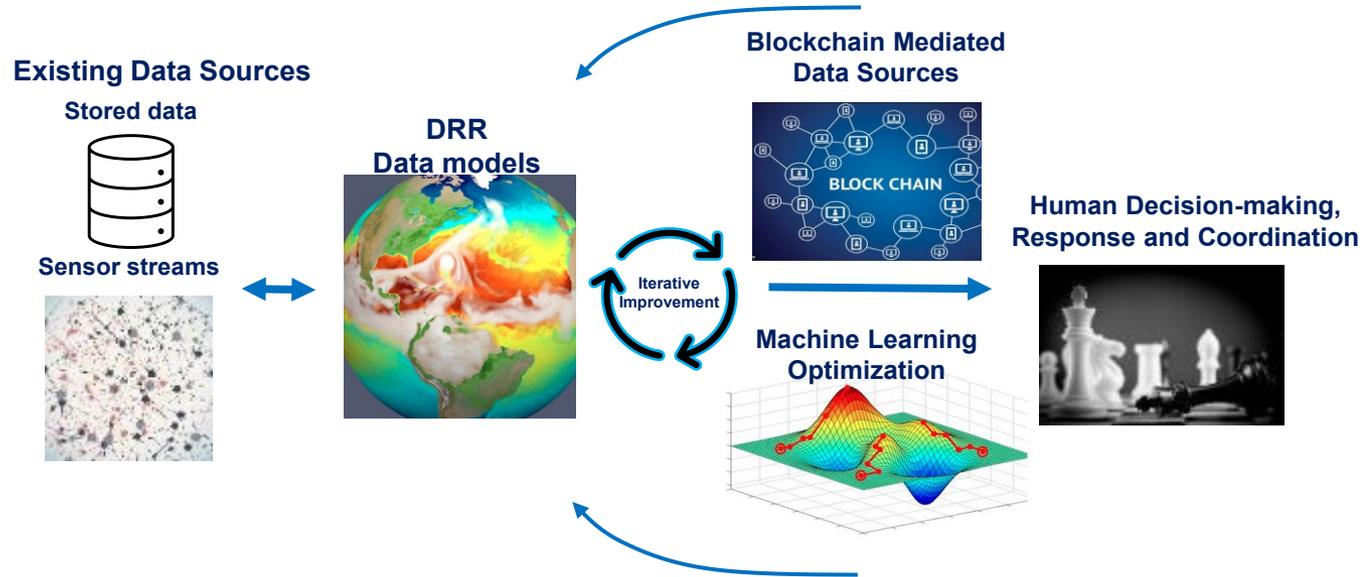

Earthquake impact

Hurricanes 2008 – Fay, Gustav, Hannah

Blockchain-mediated data model enhancement

Blockchain features and value

Technical

No central administrator to assure trust

- There is no “god”
- There are many angels

Distributed ledger

- No one owns the transaction record
- Multiple sources of validation

Consensus algorithms

- Proof of Work, Proof of Stake
- Only one valid chain
- Resolution of competing chains

Smart contracts

- Complex conditions for transactions
- Not in original blockchain, Ethereum

Business

Identity /trust

- Trust
- Non-repudiation
- Anonymization / confidentiality

Provenance

Ownership – Virtual objects

- Payments
- Data
- Services
- Treatment regimens

Transferability

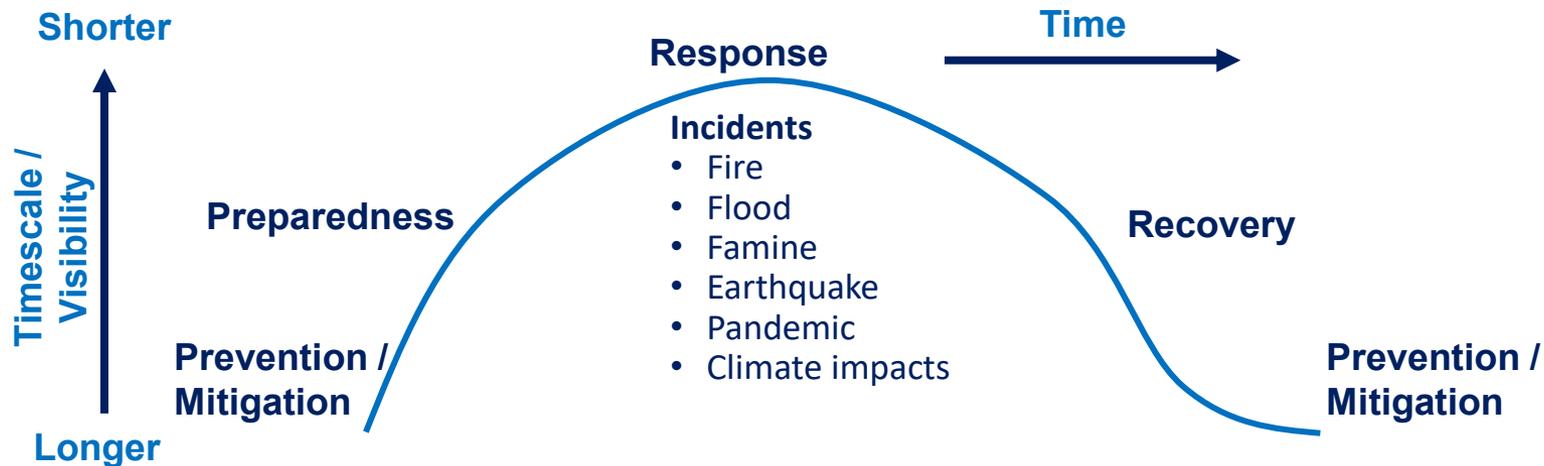

Anonymization / Confidentiality

Governance

- Pervasive rule-based contracts and verification (Smart Contracts)

Blockchain for DRR processes

Addressing 1) Risk, 2) Governance, 3) Resilience, 4) Preparedness

Blockchain Applications

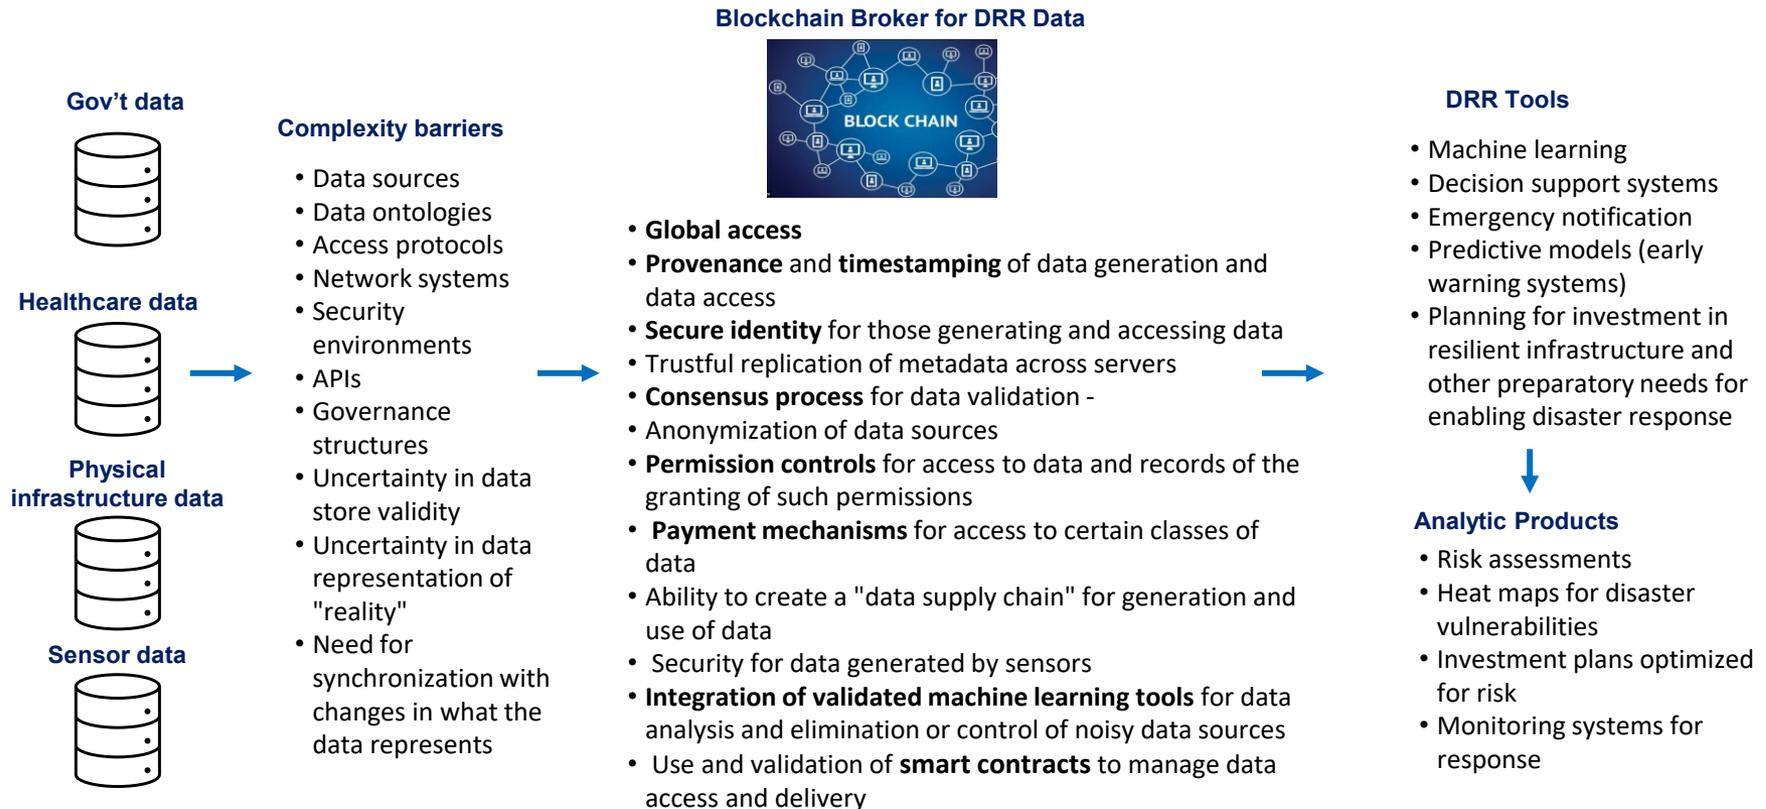

- Asset registration
- Personal / entity identity
- Data access, permissioning, validation
- Transaction records and conditions (supply chain)
- Contracts management

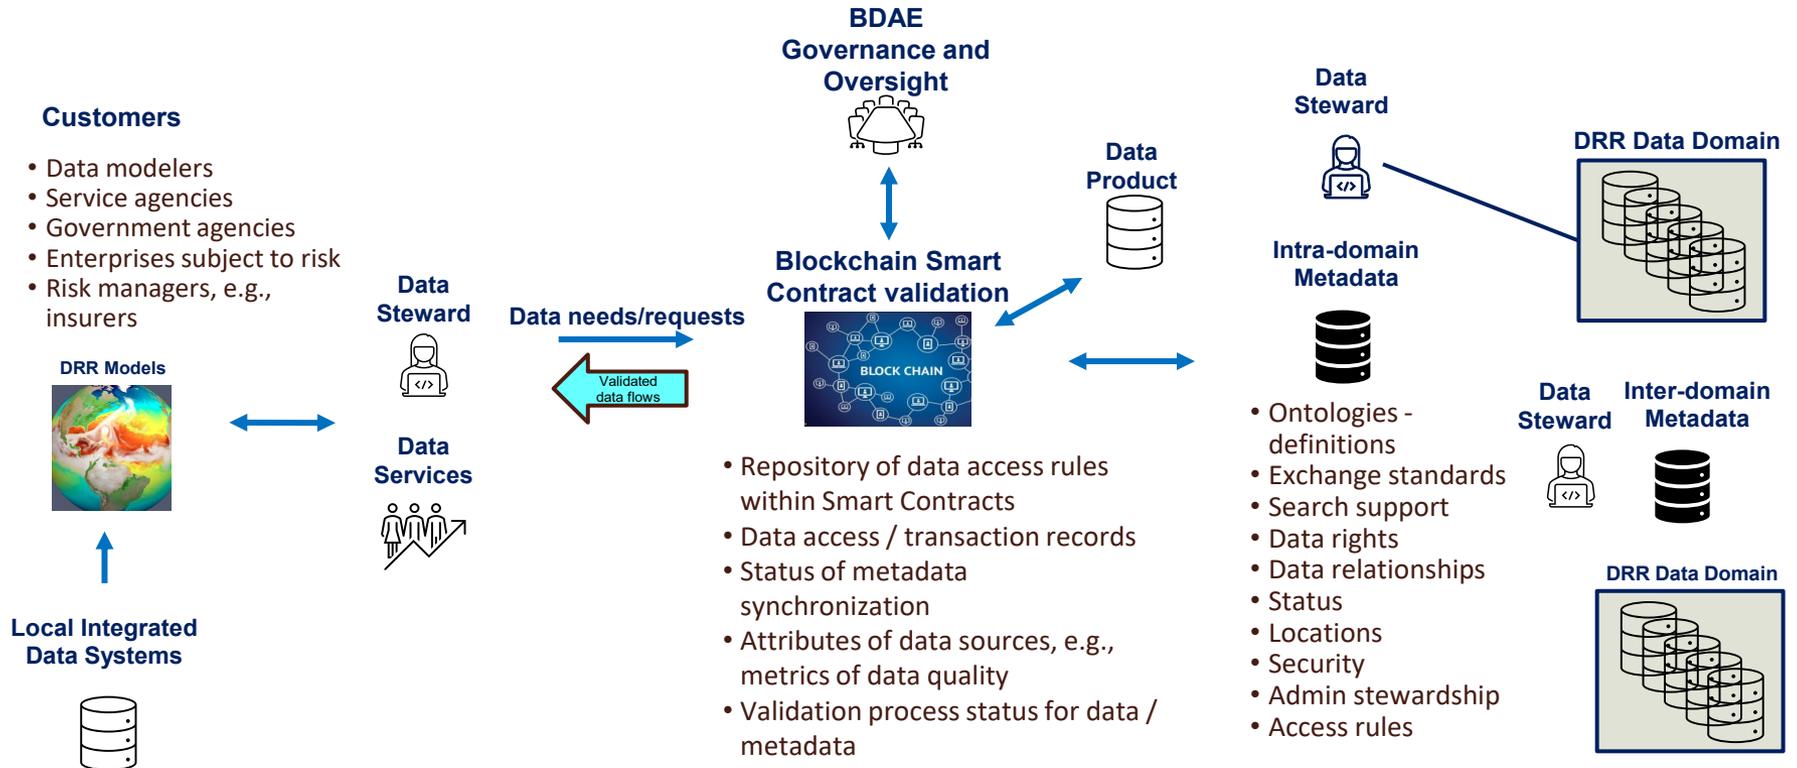

DRR Impact

- Funds and outcomes tracking
- Health data infrastructure – disease and vaccination tracking
- Predictive modeling – disaster risk mapping
- Carbon accounting and trading
- Infrastructure certification
- Resource allocation, distribution, and balancing
- Monitoring – GPS and IoT data integration and security

Blockchain-based data access process

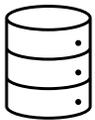

Data and metadata stewardship and validation

Experimental design

Select target set of data

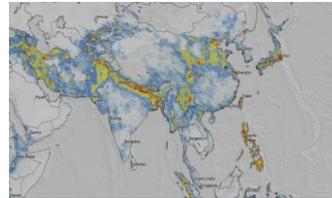

Implement Blockchain Smart Contracts to Validate/authorized data

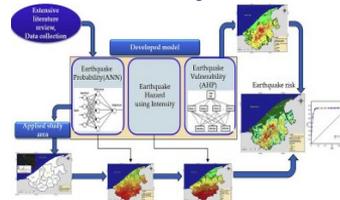

Track Use of Data in Models

Global Earthquake Hazard and Risk Models

Local Earthquake Vulnerability Models

Emergency Response Capability Models

Assess Value of Data to Model Customers

- Public health authorities
- Emergency response agencies
- Insurance companies
- Authorities regulating infrastructure
- Public and private service organizations

DRR challenges

- Cognitive obstacles to future orientation, consequences of exponential change, tipping point processes
- No magic bullet –
 - Multiple cumulative risks – Energy use, food production, permafrost thawing, ocean storage limits, embedded infrastructure
 - Multiple solutions – green energy, carbon transparency
- Lack of incentives for local change in behavior and investment
- Means for global coordination – first mover issues
- Compressed timeline for action – critical importance of the next two decades
- Disparate frames of reference for policy makers and technologists

“Remember son, there’s no future in big antlers.” — wise mother elk.
Just because a system has evolved, doesn’t mean it’s good.

Questions

- What are the most promising pilot types for Blockchain and DRR? Criteria for selecting candidates? **(e.g., time-frame, impact, resource requirements, risks)**
- What are the targets for funding sources?
- What are appropriate metrics?
- What governance mechanisms should oversee Blockchain applications for DRR?
- How can we promote the growth of communities of interest like this one and relationships with other groups?
- What publication topics would best serve our objectives?
